The efficiency rating depends on pulley size, pulley wear, V-belt alignment, transmitted torque, and if belts are under- or over-sized for specific load requirements. If the belt is not periodically retensioned, power efficiency can deteriorate by as much as 5 percent over time due to slippage. 2.

In practice, more than one type of belt misalignment can exist at the same time. Unless belt misalignment is corrected, a new belt will last no longer than the one it replaced. There are two ways to align pulleys: Traditional and laser. Traditional alignment methods are quick but often inaccurate. With these methods, mechanical tools such as straightedges, tape measures, wire, string, feeler gauges, spirit levels and calibrated cones are used.

The standard tolerance limit for V-belt drive alignment is 0.5 degrees, and 0.25 degrees for synchronous drives. Most major belt and pulley manufacturers specify these tolerance alignment values. Pulley alignment can be set closer than this if the alignment procedure is carefully followed. The following table converts degrees of misalignment to mils/inch and mm/100 (of pulley diameter) of misalignment between the projected planes of the pulley faces.
